ABSTRACT

The malacofauna of Java has been most studied among the Indonesian islands, but the list of land snails in the area remains outdated. This study presents an updated check list of land snails in Java and its adjacent islands. This list is a compilation data from field work in Java conducted in 2013-2016, records from various museums in Europe and Indonesia, collections from private collectors, data from citizen sciences, and literatures. In total, 263 land snail species were recorded in Java and its adjacent islands. The number comprises of 36 families i.e. Subclass Neritimorpha (2 families), Caenogastropoda (6 families), and Heterobranchia (28 families). About 40% are species endemic to Java and among them have restricted distribution to certain areas. In addition, 5% or 13 introduced species were recorded in Java.

Key words: biodiversity, Gastropoda, Indonesia, Mollusca, terrestrial

INTRODUCTION

Java is among the main islands in Indonesia which covers 129km² or 6.7% of the whole of archipelago (BPS, 2017). Administratively, Java is divided into six provinces: Banten, DKI Jakarta, West Java, Central Java, DI Yogyakarta, and East Java. It is located between 6° 37'18" S (Panaitan Island, Banten) to 7°11'18" S (Kangean Islands, East Java) and 112° 38'47" E (Bawean Island, East Java) to 114°31'34" E (Alas Purwo, East Java). The island is covered by volcanic features, alluvial sediments, and areas of uplifted coral limestone. During the Quaternary period, the size of Java's land coverage changed due to the sea-level fluctuations. Nevertheless, the lowland and montane forest in the area were larger in the Last Glacial Maximum (LGM) compared to the present condition (Cannon et al., 2009). The forest present today in Sumatra, Borneo, Peninsular Malaysia, and Java are believed to be refugia for the region's biodiversity.

Java is the most populous island in the world and, accordingly, most of its area has been strongly modified by man. The island has suffered massive land use change throughout time. The area was divided into several land use types where only 5% of the island is covered by natural forest (Whitten et al., 1997; Purba et al., 2014). Forest in Java covers a total of 3,086,200 ha, consisting of 74,100 ha of primary forest, 788,200 ha of secondary forest and 2,240,000 ha of plantations (KLHK, 2016). The greatest threat to forest areas in Java today comes from anthropogenic factors, i.e. land conversions (forest destruction). In addition to

habitat loss, the existence of forest inhabitants is also endangered by hunting/trade, invasive alien species, and climate change (Hughes, 2017).

There are 27,474 described land snails in the world (Molluscabase.org, 2021). Yet, the scientific knowledge of the species diversity is scarce. Land snail species tend to have very small ranges, sensitive to changes associated with human disturbance, and are, thus, especially prone to extinction by habitat destruction (Schilthuizen et al., 2005; Douglas et al., 2013).

The work of land snails in Java is the most complete compared to other islands in the Indonesian archipelago. The earliest recorded discovery of land snail in Java was conducted by Johan Coenraad van Hasselt (JC van Hasselt) in 1821-1823 and recorded 40 land snail species (Martens, 1867). The most comprehensive systematic work on land snails in Java was by Möllendorf (1897) and van Benthem Jutting (1941, 1948, 1950, 1952) who described 71 species and 171 species respectively. In addition, Vermeulen (1996) discovered four new species and added the list.

The number of land snail research in Java are also growing in the 21st century (Dharma, 2005; Heryanto et al., 2003; Heryanto, 2008, 2011, 2012, 2017; Marwoto, 2011; Nurinsiyah, 2015; Nurinsiyah et al., 2016; Nurinsiyah & Hausdorf, 2019; Mujiono & Priawandiputra, 2020; Nurinsiyah & Hausdorf, 2020; Nurhayati et al., 2021). In addition, discoveries of new land snail species in Java are rising (Dharma, 2007, 2014; Nurinsiyah & Hausdorf, 2017a, 2017b; Greke, 2019; Nurinsiyah et al., 2019). In this paper, I aim to provide an updated checklist of land snails in Java and its adjacent islands, which administratively belong to the provinces in Java.

MATERIALS AND METHODS

The study is based on the material collected from field survey in Java and surrounding islands including Sempu and Madura Islands in 2013-2016. The list was also based on the examination of land snail collections from the Museum Zoologicum Bogoriense, Bogor, Indonesia (MZB), the Natural History Museum, London, United Kingdom (NHM), the Naturalis Biodiversity Center, formerly Rijksmuseum van Natuurlijke Historie, Leiden, The Netherlands (RMNH), the Senckenberg Museum, Frankfurt, Germany (SMF), the former Zoologisch Museum, Amsterdam, The Netherlands (ZMA; now in the RMNH), the Museum für Naturkunde, Berlin, Germany (ZMB), and the Zoological Museum of the University of Hamburg, Germany (ZMH). Finally, the list was completed with literature study. The checklist covers land snails from the Java mainland as well as its adjacent islands for instance the Panaitan, Peucang, and Dua islands (Banten), thousand islands in Jakarta Bay, Nusa Kambangan (Central Java), Sempu, Nusa Barung, Madura, Bawean and Kangean islands

(East Java). I excluded the list of land snails from Krakatau Islands because administratively they belong to Lampung Province (Sumatra).

Identification and validation processes referred to van Benthem Jutting (1948, 1950, 1952), Loosjes (1953), Butot (1955), Winter (1983), Dharma (1992, 2007, 2014), Winter & Vermeulen (1998), Vermeulen & Whitten (1998), Gomes & Thomé (2004), Heryanto (2011), and Páll-Gergely et al. (2020). The systematic arrangement and taxonomy status of the determined gastropods follows the classification of Bouchet et al. (2017) and Molluscabase.org.

RESULTS

A total of 263 land snail species of 36 families, i.e. Subclass Neritimorpha (2 families), Caenogastropoda (6 families), and Heterobranchia (28 families) were recorded in Java and adjacent islands (Table 1). Among them, 246 species were recorded in the main island of Java. Seventeen species were recorded only in the adjacent islands and not on the main island of Java. About 40% (104 species) of the 263 land snail species recorded were endemic to Java and its adjacent islands.

Many of the endemic species in Java are restricted to a small region. Among the total number of species that occur in Java, 53% (139 species) were recorded in karst areas. Twenty-five species occur exclusively in karst areas. Each of the fourteen of these karst-exclusive species were each found only in a single karst area. For instance, among 27 *Landouria* species in Java, 21 species have restricted distributions and are only recorded in small range areas in Java (Nurinsiyah et al., 2019). From 23 diplommatinids, 12 species were recorded only in non-karst (volcanic/mountain) areas. The records of these small range endemic forest species might indicate that small scale forest refugia probably existed during the glacial period.

DISCUSSION

Based on the extremely high species richness of plants and vertebrates, Indonesia is listed as one of the mega diversity countries (Reid, 1998). Furthermore, the country is also included among the 25 biodiversity hotspots (Sundaland) based on the number of endemic species and the degree of threat (Myers et al., 2000). Fourteen percent of the land snail species known in Indonesia occur in Java (Hausdorf, 2019). The number of land snail species in Java is slightly differ from Sumatra and Sulawesi, which have larger areas (Table 2). The land snail species diversity in the two latter islands might be underestimated due to

the lack of malacological study in these areas. This is the case not only for snails, but also for other invertebrate taxa that are often neglected.

Table 2. Land snail species diversity in the archipelago (source: adapted from Hausdorf, 2019)

Island	Area (km ²)	Number of Species
Sumatra	473,481	276
Java & adjacent islands	129,438	263
Bali & Nusa Penida	5,780	126
Borneo	743,330	558
Sulawesi	180,680	253

The 263 land species in Java and adjacent islands is a great increment from the previous comprehensive list which was 171 land snail species (van Benthem Jutting, 1941, 1948, 1950, 1952). The additional species came from new record of native species, new record of introduced species, and newly described species. In the past two decades there were 26 new species of Gastropods have been described from Java. There were also fossil species of Gastropods described (Dharma, 2007, 2021) but they are not included in the list. Whitten et al. (1997) listed seven introduced species from Java i.e. *Allopeas gracile*, *Lissachatina fulica*, *Subulina octona*, *Gulella bicolor*, *Rachis zonulata*, *Gastrocopta servilis*, and *Bradybaena similaris*. The number was added to 13 introduced species (Nurinsiyah & Hausdorf, 2019). The widely distributed introduced species occur mainly in the disturbed areas and modified habitats. The proportion of introduced species abundance in an area can be used as indicator for habitat disturbance (Nurinsiyah et al., 2016).

Among the 17 land snail species found on the adjacent islands (not in mainland), nine species are endemic to a particular island. The species of *Geophorus rollei*, *Cyclotus kangeanus*, *Hemiplecta kangeanensis*, and *Landouria kangeanensis* were found only in Kangean island (van Benthem Jutting, 1941). The island is located more than 120km from the mainland Java even though administratively belongs to the Province of East Java. There are also species endemic to adjacent island located less than 1km away from the mainland Java. *Dicharax candrakirana* is endemic to Sempu Is. and *Landouria nusakambangensis* is endemic to Nusa Kambangan Is. (Nurinsiyah & Hausdorf, 2017b; Nurinsiyah et al., 2019). The former island is a nature reserve, whereas the latter is a prison island which public have limited access to enter the area. However, there is a concession area for limestone quarry in the northern part of the Nusa Kambangan Is. Although more than 50% of the concession area is designated for conservation forest, land coverage and habitat sustainability for the forest inhabitants needs to be ensured.

Terrestrial mollusk is one of the fauna groups that is often overlooked and abandoned from the conservation spotlight. It was estimated that this group may have lost 7% of the total described species on Earth (Régnier et al., 2015). Although the work of land snails in Java is the most complete compared to other islands in the Indonesian archipelago, monitoring the sustain population in Java is crucial. Furthermore, there will always be a yet discovered taxa or systematically problematic taxa in this well-known island awaiting scientific discovery.

ACKNOWLEDGEMENTS

I am grateful to Prof. Bernhard Hausdorf (Centrum für Naturkunde, Universität Hamburg) for supervising the research; Tedi Setiadi for the help in this study; Alfiah, Heryanto, N. Isnatingsih, R. Marwoto, N. Mujiono, and R. Prihandini from the Museum Zoologicum Bogoriense Indonesia for providing resources and help in laboratory work; A.F. Bakti (Bandung), H. Cahyono (Malang), I. Faizah (Lebak), H. Fauzia (Malang), F. Irsyad (Bandung), Kaspo (Yogyakarta), H. Mada (Bandung), R. Nasrullah (Tasikmalaya), E. Nurlela (Bandung), Y. Prasetio (Kabandungan), M. Rizky (Tasikmalaya), and F. Sari (Bandung) for assistance in field and laboratory work. I also thank Barna Páll-Gergely, Thor Seng Liew, and Gizelle Batomalaque for the comments and suggestions for the improvement of this manuscript. The study was supported by the Indonesian-German Scholarship Program (KEMENDIKTIRISTEK-RI and DAAD), the University of Hamburg, the Conchologist of America, and BMBF (INDOBIOSYS MfN Berlin, 16GW0111K).
