## **Editor's Note**

Another yearly volume of Treubia is published. I have only recently become involved in the publication of this journal and I can say that the research in this issue is increasingly interesting. I hope to remain actively involved in the publication of this journal and that we can continue to reach a larger audience as time goes on.

This volume of TREUBIA contains 5 papers of vertebrates and invertebrates. The contents of these papers vary widely from vocalizations of frogs to tropical forest spider communities. I can only hope in the future that we continue to receive interesting submissions from all areas of zoology of the Indo-Australian Archipelago.

Also this year two esteemed colleagues from LIPI retired from the service of science, Dr. Mas Noerdjito who studied the ecology of birds and Dr. Agustinus Suyanto who dedicated his life to the study of mammals.

Finally I would like to thank all of the co-editors, referees, computing assistants, secretaries and administrative assistants for their collaborative work without which this journal could not be published. I also acknowledge financial support from the Director of Research Center for Biology, LIPI to publish this essential journal.

### ABSTRACT

A total of 383 vespid species belonging to 63 genera from Indonesia are listed, together with information of the type material deposited in the Museum Zoologicum Bogoriense (MZB). The references of their distribution in Indonesia are also provided.

**Keywords:** Hymenoptera, Vespidae, Eumeninae, Stenogastrinae, Polistinae, Vespinae, checklist, Indonesian Archipelago

### INTRODUCTION

The hymenopteran family Vespidae, with more than 5,000 species worldwide, is divided into six monophyletic subfamilies (Carpenter, 1981, 2003; Pickett and Carpenter, 2010). The phylogenetic relationships among the subfamilies are Euparagiinae + (Masarinae + (Eumeninae + (Stenogastrinae + (Polistinae + Vespinae)))). The wasps in the clade Stenogastrinae–Vespinae are social, while those in the three basal subfamilies are solitary (Carpenter, 1981). Except for the masarines, the vespid wasps are predaceous on terrestrial insects, and they are more or less at higher positions in a food-web of terrestrial arthropods. The masarines are anthophilic and have been shown to be pollinators. The vespid wasps in the other subfamilies, though they are predaceous, also visit various flowers for nectar as their own energy source and thus are, at least potentially, pollinators of many plants (Kojima, 1993; Carpenter and Wenzel, 1999). These considerations suggest that the vespid wasps play important roles in an ecosystem, and thus they can be good bio-indicators for environmental conditions and/or habitat

perturbation. Also, because of their predaceous habits, the vespidae wasps have the potentiality to be effective biological control agents.

In Southeast Asia and the Papuan region, where several biodiversity hotspots are recognized, four of the six vespidae subfamilies occur. Eumeninae are cosmopolitan and include more than 3,500 described species (Pickett and Carpenter, 2010: table 1), however, the tropical faunas are very poorly known. Stenogastrinae, with 58 currently valid species in seven genera, are distributed from India in the west to New Guinea in the east. Polistinae are cosmopolitan, with slightly less than 1,000 species in 25 genera; the subfamily is divided into the following four tribes: cosmopolitan Polistini (= *Polistes*; 218 species), New World endemic Mischoctytarini (= *Mischocyttarus*; 246 species) and Epiponini (234 species in 19 genera), and Old World endemic Ropalidiini (269 species in four genera). The subfamily Vespinae, with 67 species in four genera, is more northern in distribution than its sister-group, the Polistinae; *Dolichovespula* (18 species) and *Vespa* (24 species) are predominantly holarctic, *Vespa* (22 species) is Palearctic and Oriental, and *Provespa* (3 species) occurs only in Southeast Asia.

Indonesia is an archipelago country consisting of about 17,500 islands spreading eastward from Sumatra to New Guinea, and also known as a country of megabiodiversity. As the basis for intensive study on the species-level biodiversity of the Vespidae in Indonesia, the present checklist provides basic taxonomic information and distribution records for the vespidae wasps so far recorded from Indonesia. Simply because all the borders with Malaysia on Borneo Island, with East Timor on Timor Island and with Papua New Guinea on New Guinea Island may have no biological meaning, the species so far recorded only from Sarawak and Sabah of Malaysia, Brunei, East Timor or Papua New Guinea are also included in the list.

In each subfamily, the genera are listed alphabetically and species are numbered, with a sub-number for each subspecies, if any. Species and subspecies names are listed alphabetically in each genus insofar they are considered as valid in the most recent citation. Each species-group taxon name so far considered is accompanied by the original citation, followed by primary synonym(ies). Sex(es) if mentioned and locality(ies) in the original citation are given together with the depository(ies) of name-bearing type specimen(s) in parentheses. Distributional data are summarized under "Distribution:" by country, with references only for records from Indonesia. "Papua" refers to the Indonesian part of New Guinea, formerly known as Irian Jaya. Notes on the type material deposited in the Museum Zoologicum Bogoriense (MZB) are also provided.

#### Genus *Kennethia* Giordani Soika, 1994

This name is a junior homonym of *Kennethia* De Dekker, 1979 (Ostracoda), and hence it is not available. *Kennetia* Giordani Soika, 1994, is an incorrect original spelling of *Kennethia* Giordani Soika, 1994. Furthermore in p. 290, Giordani Soika gave etymology for a genus

name: “Dedicato al mio collaboratore ed amico Kenneth Guichard”. Although the spelling *Kennetia* was used under the heading of new genus, this would seem to be internal evidence of an inadvertent error, and so *Kennetia* is not available (Art. 32.5.1.1). We here list *Kennethia* Giordani Soika, 1994 for the purpose of cataloging.

Distribution: Papua New Guinea.

### Tribe **Ropalidiini**

Of the four ropalidiine genera, *Ropalidia* (nearly 180 species) occurs throughout the Old World tropics and subtropics, and shows considerable divergence in Madagascar and Papuan region (Kojima and Carpenter, 1997). *Parapolybia*, with five species currently recognized as valid, is distributed from Middle East in the west to New Guinea in the east, and the wasps of the genus seem to be more abundant in terms of population density in subtropics and temperate regions than in tropics. *Polybioides*, with six species, shows a peculiar disjunct distribution pattern; two species are endemic to continental Africa and the remaining four species occur in Southeast Asia. The genus *Belonogaster* is African (including Madagascar), with one species recorded from India.
